

Naive Bayesian

The Naive Bayesian classifier is based on Bayes' theorem with independence assumptions between predictors. A Naive Bayesian model is easy to build, with no complicated iterative parameter estimation which makes it particularly useful for very large datasets. Despite its simplicity, the Naive Bayesian classifier often does surprisingly well and is widely used because it often outperforms more sophisticated classification methods.

Algorithm

Bayes theorem provides a way of calculating the posterior probability, $P(c|x)$, from $P(c)$, $P(x)$, and $P(x|c)$. Naive Bayes classifier assume that the effect of the value of a predictor (x) on a given class (c) is independent of the values of other predictors. This assumption is called class conditional independence.

$$P(c|x) = \frac{P(x|c)P(c)}{P(x)}$$

Likelihood
Class Prior Probability
Posterior Probability
Predictor Prior Probability

$$P(c|X) = P(x_1|c) \times P(x_2|c) \times \dots \times P(x_n|c) \times P(c)$$

- $P(c|x)$ is the posterior probability of *class (target)* given *predictor (attribute)*.
- $P(c)$ is the prior probability of *class*.
- $P(x|c)$ is the likelihood which is the probability of *predictor* given *class*.
- $P(x)$ is the prior probability of *predictor*.

Example:

The posterior probability can be calculated by first, constructing a frequency table for each attribute against the target. Then, transforming the frequency tables to likelihood tables and finally use the Naive Bayesian equation to calculate the posterior probability for each class. The class with the highest posterior probability is the outcome of prediction.

$P(x|c) = P(\text{Sunny} | \text{Yes}) = 3 / 9 = 0.33$

Frequency Table		Play Golf	
		Yes	No
Outlook	Sunny	3	2
	Overcast	4	0
	Rainy	2	3

→

Likelihood Table		Play Golf		
		Yes	No	
Outlook	Sunny	3/9	2/5	5/14
	Overcast	4/9	0/5	4/14
	Rainy	2/9	3/5	5/14
		9/14	5/14	

$P(c) = P(\text{Yes}) = 9 / 14 = 0.64$

$P(x) = P(\text{Sunny}) = 5 / 14 = 0.36$

Posterior Probability: $P(c|x) = P(\text{Yes} | \text{Sunny}) = 0.33 \times 0.64 \div 0.36 = 0.60$

The zero-frequency problem

Add 1 to the count for every attribute value-class combination (*Laplace estimator*) when an attribute value (*Outlook=Overcast*) doesn't occur with every class value (*Play Golf=no*).

Numerical Predictors

Numerical variables need to be transformed to their categorical counterparts ([binning](#)) before constructing their frequency tables. The other option we have is using the distribution of the numerical variable to have a good guess of the frequency. For example, one common practice is to assume normal distributions for numerical variables.

The probability density function for the normal distribution is defined by two parameters (mean and standard deviation).

$$\mu = \frac{1}{n} \sum_{i=1}^n x_i \quad \text{Mean}$$

$$\sigma = \left[\frac{1}{n-1} \sum_{i=1}^n (x_i - \mu)^2 \right]^{0.5} \quad \text{Standard deviation}$$

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \quad \text{Normal distribution}$$

Example:

		Humidity										Mean	StDev
Play Golf	yes	86	96	80	65	70	80	70	90	75	79.1	10.2	
	no	85	90	70	95	91					86.2	9.7	

$$P(\text{humidity} = 74 | \text{play} = \text{yes}) = \frac{1}{\sqrt{2\pi}(10.2)} e^{-\frac{(74-79.1)^2}{2(10.2)^2}} = 0.0344$$

$$P(\text{humidity} = 74 | \text{play} = \text{no}) = \frac{1}{\sqrt{2\pi}(9.7)} e^{-\frac{(74-86.2)^2}{2(9.7)^2}} = 0.0187$$

Predictors Contribution

Kononenko's *information gain* as a sum of information contributed by each attribute can offer an explanation on how values of the predictors influence the class probability.

$$\log_2 P(c|x) - \log_2 P(c)$$

The contribution of predictors can also be visualized by plotting [nomograms](#). Nomogram plots log odds ratios for each value of each predictor. Lengths of the lines correspond to spans of odds ratios, suggesting importance of the related predictor. It also shows impacts of individual values of the predictor.

[Exercise](#)

[Naive Bayesian Interactive](#)

Try to invent a real time Bayesian classifier. You should be able to add or remove data and variables (predictors and classes) on the fly.
